Highlights

The Boussinesq–compressible gap in steady two-dimensional buoyancy-driven enclosure convection is linear to leading order in the relative temperature contrast

- The gap follows $R = A\varepsilon(1 + \kappa\varepsilon)$; window-averaged exponent 1.02, 627 pairs
- Temperature contrast alone breaks the symmetry; a 24$\times$ Ma change is below resolution
- Correction factorises as $D = \varepsilon P(X)$: networks learn only the spatial shape
- One inference takes 6.3 ms; per-pair cost falls 2.9$\times$ and 13$\times$ for a 20$\times$5 scan
- A wall-flux loss cuts the predicted integral Nu error to 0.11% (doing nothing: 0.67%)
